La dr.ssa Maria Chantal Ponziani dichiara di NON aver ricevuto negli ultimi due anni compensi o finanziamenti da Aziende Farmaceutiche e/o Diagnostiche

Dichiara altresì il proprio impegno ad astenersi, nell'ambito dell'evento, dal nominare, in qualsivoglia modo o forma, aziende farmaceutiche e/o denominazione commerciale e di non fare pubblicità di qualsiasi tipo relativamente a specifici prodotti di interesse sanitario (farmaci, strumenti, dispositivi medico-chirurgici, ecc.).

PCSK9 Regulates LDLR Turnover Through Increased Intracellular Degradation

This research was originally published in Journal of Lipid Research. Lambert G, et al. The PCSK9 decade. *J Lipid Res.* 2012; 53: 2515–24. © the American Society for Biochemistry and Molecular Biology.

Loss-of-Function Mutations in PCSK9 Are Associated With Decreased LDL-C and CHD Risk

PCSK9 Variant	Population	LDL-C	CHD Risk
R46L	ARIC, DHS	↓ 15% ¹	↓ 47% ¹
Y142X or C679X	ARIC, DHS	↓ 28%-40% ^{1,2}	↓ 88% ¹
R46L	CGPS	↓ 11% ³	↓ 46% ³

- Heterozygous LOF mutations found in 1% to 3% of population¹
- Associated with
 - Lower serum LDL-C¹
 - Lower incidence of coronary heart disease¹
- PCSK9 null individual identified (compound heterozygote for two inactivating mutations)
 - No detectable circulating PCSK9 with strikingly low LDL-C (14 mg/dL)⁴
 - Healthy and fertile college graduate in apparent good health⁴
- Inhibiting LDLR/PCSK9 interaction may lower plasma LDL-C levels⁵

LOF = loss of function.

Table 1. Plasma Lipid and Lipoprotein Levels in Family Members of an Individual Who Is a Compound Heterozygote for Loss-of-Function Mutations in PCSK9

Individual	Age (years)	Sex	Fasting Plasma Levels, in mg/dL (Percentile)				PCSK9 Allele ^a	
			Cholesterol	LDL-C	HDL-C ^b	TG ^c	1	2
I.1	51	M	96 (<1st)	39 (<1st)	44 (55th)	88 (25th)	ΔR97	WT
I.2	53	F	144 (<1st)	49 (<1st)	88 (90th)	51 (<1st)	Y142X	WT
II.1	10	F	137 (15th)	77 (20th)	49 (45th)	78 (50th)	ΔR97	WT
II.2	32	F	96 (<1st)	14 (<1st)	65 (80th)	119 (70th)	ΔR97	Y142X
II.3	28	F	152 (20th)	80 (15th)	59 (65th)	92 (55th)	WT	WT
III.1	6	M	106 (<1st)	30 (<1st)	65 (75th)	77 (75th)	Y142X	WT
III.2	3	F	106 (<1st)	37 (<1st)	59 (70th)	71 (55th)	Y142X	WT
III.3	13	F	174 (60th)	104 (60th)	55 (65th)	110 (75th)	WT	WT

NOTE.—Plasma lipid and lipoprotein levels were measured after a 12-h fast. The percentile of the lipid and lipoprotein levels are compared with age- and sex-matched African American control individuals.

^a WT = wild type.

^b HDL-C = high-density lipoprotein cholesterol.

^c TG = triglycerides.

PCSK9 GAIN-of-Function Mutation: Identifying the Cause and a Potential Treatment Target

Mutations in *PCSK9* cause autosomal dominant hypercholesterolemia

Autosomal dominant hypercholesterolemia (ADH; OMIM144400), a risk factor for coronary heart disease, is characterized by an increase in low-density lipoprotein cholesterol levels that is associated with mutations in the genes *LDLR* (encoding low-density lipoprotein receptor) or *APOB* (encoding apolipoprotein B). We mapped a third locus associated with ADH, *HCHOLA3* at 1p32, and now report two mutations in the gene *PCSK9* (encoding proprotein convertase subtilisin/kexin type 9) that cause ADH. *PCSK9* encodes NARC-1 (neural apoptosis regulated convertase), a newly identified human subtilase that is highly expressed in the liver and contributes to cholesterol homeostasis.

CHD, coronary heart disease.

L'INSULINA AUMENTA L'ESPRESSIONE DI PCSK9 A LIVELLO EPATICO

The Role of Insulin in the Regulation of PCSK9

Published in final edited form as:
Arterioscler Thromb Vasc Biol. 2015 July ; 35(7): 1589–1596

Ji Miao¹, Praveen V. Manthena¹, Mary E. Haas¹, Alisha V. Ling¹, Dong-Ju Shin¹, Mark J. Graham², Rosanne M. Crooke², Jingwen Liu³, and Sudha B. Biddinger¹

Approach and Results—Using rat hepatoma cells and primary rat hepatocytes, we found that insulin increased PCSK9 expression and increased LDL receptor degradation in a PCSK9-dependent manner. In parallel, hepatic *Pcsk9* mRNA and plasma PCSK9 protein levels were reduced by 55-75% in mice with liver-specific knockout of the insulin receptor; 75-88% in mice made insulin deficient with streptozotocin; and 65% in *ob/ob* mice treated with antisense oligonucleotides against the insulin receptor. However, antisense oligonucleotide mediated knockdown of insulin receptor in lean, wildtype mice had little effect. In addition, we found that fasting was able to reduce PCSK9 expression by 80% even in mice that lack hepatic insulin signaling.

PCSK9 genetic variants and risk of type 2 diabetes: a mendelian randomisation study

www.thelancet.com/diabetes-endocrinology Vol 5 February 2017

Figure 2: Association of genetic variants in PCSK9 with glycaemic and anthropometric biomarkers

Effect estimates are presented as mean difference with 95% CIs. Associations were scaled to a 1 mmol/L reduction in LDL cholesterol. SNP-specific results are pooled by use of a fixed-effect model; weighted gene-centric score (GS) models combining all four SNP-specific estimates are presented as fixed-effect and random-effects estimates. The size of the black dots representing the point estimates is proportional to the inverse of the variance. Between-SNP heterogeneity was measured as a two-sided Q-test (χ^2) and an I^2 with one-sided 97.5% CI. Note that results from individual participant data are supplemented by repository data from the Global Lipids Genetics Consortium, the Meta-Analyses of Glucose and Insulin-related traits Consortium, and the Genetic Investigation of Anthropometric Traits consortium.

Figure 4: Correlation between PCSK9 associations with LDL cholesterol concentration and type 2 diabetes

Effect estimates are presented as mean difference in LDL cholesterol concentration (mmol/L) and odds ratios (ORs) for the incidence or prevalence of type 2 diabetes, with 95% CIs. Associations are presented per LDL cholesterol-decreasing allele. The Pearson correlation coefficient, regression line (grey), and its 95% CI (red) were calculated by weighting the SNPs for the inverse of the variance in the type 2 diabetes association. Excluding the SNP with the largest effect on LDL cholesterol (rs11591147) resulted in a correlation coefficient of 0.993 and a p value of 0.437.

Combination Therapy as First-Line Strategy in Very High-Risk Patients

Evolocumab

- *pazienti di età ≤ 80 aa con ipercolesterolemia familiare omozigote - in prevenzione primaria in pazienti di età ≤ 80 aa con ipercolesterolemia familiare eterozigote e livelli di LDL-C ≥ 130 mg/dL nonostante terapia da almeno 6 mesi con statina ad alta potenza alla massima dose tollerata + ezetimibe oppure con dimostrata intolleranza alle statine (vedere successivamente la definizione di intolleranza) e/o all'ezetimibe;*
- **in prevenzione secondaria** *in pazienti di età ≤ 80 aa con ipercolesterolemia familiare eterozigote o ipercolesterolemia non familiare o dislipidemia mista con livelli di LDL-C ≥ 70 mg/dL nonostante terapia da almeno 6 mesi con statina ad alta potenza alla massima dose tollerata + ezetimibe oppure dopo una sola rilevazione di C-LDL in caso di IMA recente (ultimi 12 mesi) o eventi CV multipli oppure con dimostrata intolleranza alle statine (vedere successivamente la definizione di intolleranza) e/o all'ezetimibe.*

Alirocumab

Inclisiran

- *in prevenzione primaria in pazienti di età ≤ 80 aa con ipercolesterolemia familiare eterozigote e livelli di LDL-C ≥ 130 mg/dL nonostante terapia da almeno 6 mesi con statina ad alta potenza alla massima dose tollerata + ezetimibe oppure con dimostrata intolleranza alle statine (vedere successivamente la definizione di intolleranza) e/o all'ezetimibe;*
- **in prevenzione secondaria** *in pazienti di età ≤ 80 aa con ipercolesterolemia familiare eterozigote o ipercolesterolemia non familiare o dislipidemia mista e livelli di LDL-C ≥ 70 mg/dL nonostante terapia da almeno 6 mesi con statina ad alta potenza alla massima dose tollerata + ezetimibe oppure dopo una sola rilevazione di C-LDL in caso di IMA recente (ultimi 12 mesi) o eventi CV multipli oppure con dimostrata intolleranza alle statine (vedere successivamente la definizione di intolleranza) e/o all'ezetimibe.*

Le dosi raccomandate di alirocumab sono 75 mg una volta ogni 2 settimane, 150 mg una volta ogni 2 settimane, 300 mg una volta ogni 4 settimane (mensilmente), somministrate per via sottocutanea. Tutte le dosi possono essere utilizzate per l'inizio del trattamento.

La dose raccomandata di evolocumab è 140 mg ogni due settimane o 420 mg una volta al mese; le due dosi sono clinicamente equivalenti.

Somministrazione^{1,2}

Uso sottocutaneo.

Inclisiran è somministrato tramite iniezione sottocutanea nell'addome; siti di iniezione alternativi comprendono il braccio o la coscia.

Ogni dose da 284 mg viene somministrata utilizzando una singola siringa preriempita.

Ogni siringa preriempita è solo monouso.

Inclisiran è destinato alla somministrazione da parte di un operatore sanitario.

Formulazione^{1,2}

- Siringa preriempita
- Ogni siringa preriempita contiene inclisiran sodico equivalente a 284 mg di inclisiran in 1,5 mL di soluzione
- Conservazione a temperatura ambiente

Regime posologico^{1,2}

Semplicemente

- I diabetici hanno nella maggior parte dei casi un rischio cardiovascolare alto o molto alto
- L'obiettivo di c LDL per tale rischio non sempre viene raggiunto con la dose massima tollerata di statina + ezetimibe
- I farmaci che agiscono su PCSK9 rappresentano una opzione terapeutica efficace e sicura
- Dai trial clinici non risulta un aumento del rischio di diabete

Grazie per l'ascolto
